

MOBILIZING PUBLIC SERVICE

A Primer for Government Agencies

Summary

Government agencies such as law enforcement and first responders have always been early users of mobile computing technologies. The reason is simple: their job duties require access to real-time information in order to safely complete their work.

As mobile computing has evolved and equipment and service costs have decreased, more government agencies are realizing the productivity increases garnered by equipping workers with laptops, tablet PCs and smart handheld devices. Now a wide array of government organizations from child and family services to public works, field inspectors and even municipal utilities are deploying mobile computing technologies to improve public service, increase worker productivity and better leverage budgetary resources.

This paper outlines examples of mobile technologies within different government agencies and details the key components that any organization should consider as they mobilize their workforce.

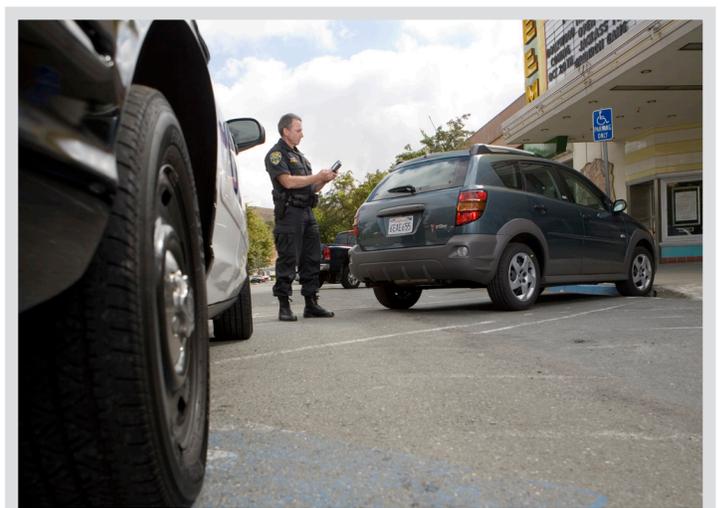

Mobile Computing for Government

Law Enforcement

In most jurisdictions, police and sheriff's departments have been the innovators in mobile computing. Typically the first application for these deployments is computer-aided dispatch (CAD) which delivers complete information about a call including address information faster than would be possible using radio-only dispatch. This speeds response time and enhances officer safety. Newer systems are more sophisticated and transmit more data, including maps and turn-by-turn directions. Officers also use computer applications and data networks to:

- Access federal Criminal Justice Information System (CJIS) data
- Update incident reports stored in records management systems (RMS) in realtime
- View images of missing children, or fingerprints or photos of suspects
- Run drivers' license checks
- Access other law enforcement information on the Internet
- Check e-mail and access departmental intranets
- Access case records, incident reports and call history for doing field investigations
- Stream video traffic from dashboard-mounted cameras

Wireless data access can save officers' time – and their lives. Immediate online access to vehicle license plate checks can return data in seconds, rather than waiting to go through a dispatcher, and instantly alert the officer that the driver is a fleeing felon who might be armed.

Police and sheriff departments have been the innovators in mobile computing. Wireless data access can save officers' time and their lives.

Emergency Medical Services

Vital medical information about patients gathered on the scene and during transport to the hospital has typically been gathered on paper forms, and entered later into EMS department systems by hand. This time-consuming double entry by EMTs and paramedics doesn't just drain productivity. It can delay treatment at the hospital as hospital workers review patient records upon arrival.

As a growing number of EMS departments have found, entering the clinical data directly into a laptop computer and transmitting it directly to the receiving hospital via wireless networks is a boon to patient care. It sends complete medical information while the patient is en route, so the medical center is fully aware of the patient's condition, can prep the treatment room beforehand and shorten the time-to-treatment.

Fire Departments

Fire departments are deploying CAD applications for the same reasons as police departments – to foster more informed, more effective and faster responses. In addition to street address, directions and incident description, sophisticated departments are using mobile data access to send response preplans. These slash minutes off the time required to gather information and assess the situation at the site, ultimately decreasing property damage and often the loss of life.

These response pre-plans can include building maps, information on suppression systems, hydrant locations and exactly where gas and power shutoffs may be accessed. Pre-plans also detail hazardous materials on-site.

Fire and EMS departments are deploying CAD applications to foster more informed, more effective and faster responses.

Responders can then use mobile data access to confirm information about the risks presented by burning materials so they can protect themselves and the public.

Some of the newest systems link with GPS systems in each vehicle so dispatchers know exactly where each unit is throughout the jurisdiction. This is extremely useful in rural counties, or in congested urban areas where transit time could be an issue. Often, a unit already deployed in the field could be closer to an incident than one in the nearest station.

Departments have also found that mobile data access eliminates double entry during fire inspections, as notes of violations and changes that impact the pre-plans can be transmitted directly to the system and updated with a single entry.

Public Works

Public works involves all kinds of tasks, from patching roads to clearing sewers to repairing park benches. These are generally outdoor jobs, in far-flung locations, requiring different kinds of tools and equipment. Most public work organizations have frequently operated with a pen and paper approach. Job assignments were determined at the beginning of each day with reports updated from the office or home following project completion.

Coordinating and scheduling crews and equipment, directing them to various locations and maximizing productive

use of the working day is a task made much easier by deploying a mobile data solution. Crews can access maps, plans and schedules, and update work orders and inspection data while still at the job sites. Reports are filed faster, project status can be reviewed on-the-fly and work completed and personnel and equipment resources better utilized.

Health, Safety and Environmental Inspection Departments

Health, safety and environmental department workers constitute a broad group of government employees that perform a variety of inspections and compliance monitoring for occupational safety and health regulations. On any given day inspectors may visit restaurant kitchens, food warehousing facilities or various job sites to ensure proper health and safety regulations are followed and complied with. Over the course of the day, they will complete multiple paper form reports, complete updates to existing reports and either fax or drop off completed paperwork for processing.

Deploying mobile devices and real-time data access via connection to cellular data networks has dramatically impacted inspector productivity. Reports and data record updates occur on the spot with violations and remediation plans filed before the inspector leaves the premises. Electronic data entry has also eliminated the need for paper forms and repetitive data entry.

Child and Family Services

CFS agencies are dedicated to improving the integration of services for children, youth, families and vulnerable populations — promoting their development and protecting them from violence, neglect, abuse and abandonment. The agencies typically provide a system of family support, juvenile justice, child care and child welfare services that promote the safety and well-being of children and adults.

CFS case workers and counselors are responsible for day-to-day visits and calls to report on adults and children in foster care, adoption, child protective services, and protective programs.

With a rising number of cases that counselors need to address on a daily basis, many CFS agencies are embracing technology as a way to handle their increased work load. Case workers and counselors are now equipped with mobile devices to replace the pen and paper notes they used to keep. Doing so has reduced the administrative burden and put more information literally at their fingertips. It's also enabled workers to spend more time in the field making more visits per day and increasing their agencies' overall efficiencies.

Municipal Utilities

Field service efficiency is a top priority for utility companies. Using mobile technologies is one of the most effective ways to increase utility worker productivity and efficiency. Deploying mobile devices to field workers allows customer information and job site info to be reviewed remotely, speeding the time for delivery of service. Whether they are checking on a gas leak, reading a gas or electric meter, or responding to a customer service request, mobile technologies enable utility companies to increase their field service efficiency and customer satisfaction.

Mobile technologies help increase utility worker productivity and efficiency.

The Elements of a Mobile Deployment

The terms mobile and remote are often used interchangeably. Both terms describe data access for field workers who are not in a fixed office, tethered to a wired LAN.

Most field workers need constant connectivity to applications throughout the working day. Whether they are working from their vehicle, a client's home or on a remote job site, access to data allows them to stay productive regardless of location.

It is useful to think of a mobile deployment as having three elements: devices, wireless networks and software.

Mobile Devices

Mobile devices are typically notebook or tablet computers, although smart phones or other handheld devices may figure into the deployment based on job requirements. Leading laptop manufacturers offer ruggedized devices designed for field use. Unlike an executive who pulls a laptop out of a protective case and uses it sporadically throughout the day, mobile government workers use their devices constantly. These devices are carried outdoors in the rain, shuffled amid stacks of papers, set on top of toolboxes, tossed across a car seat or set on a dashboard while the vehicle navigates over bumpy roads, urban streets or to off-road locations. Field-tested rugged devices are typically more costly, but these units pay for themselves in lower failure rates, incidence of damage and overall support costs. Manufacturers cite instances where units continue to function despite being dropped from great heights, exposed to water, or excessive heat.

Mobile government workers typically need field-tested rugged devices, which are more costly but pay for themselves in overall support costs.

Wireless Networks

A handful of government agencies – mostly in law enforcement – have deployed their own private radio networks for data access, but most organizations today rely on data networks maintained by cellular carriers. Although there are some perceived benefits of owning a private radio network, for disaster-planning purposes carrier networks are a better option. In times of crisis, carrier networks are typically up and running faster, providing greater accessibility over a broader coverage area. Carriers have disaster teams that move in with cell-sites-on-wheels units and fleets of vehicles in order to ensure little disruption of service during times of disaster — as opposed to a city or county that might only have a few support people to fix downed antennas or areas of lost coverage.

There are a variety of network types and standards promoted by the various carriers, promising ever-increasing speeds and data capacity. But it's important to realize that reliable coverage can be an issue especially in areas with natural and man-made barriers to coverage. Carrier coverage maps based on tower locations do not account for local conditions that can block or impede transmission (e.g. mountainous terrain, tunnels, buildings). Therefore most organizations as a practical matter may consider combining networks from two or more cellular carriers to get the reliable, blanketed coverage they need throughout their jurisdiction.

Many also supplement the cellular networks by deploying their own Wi-Fi networks, with access points at strategic locations. Typical hot spot locations are parking lots and garages, fire stations, police precinct buildings, health department stations, maintenance facilities and other neighborhood offices maintained by various public agencies.

In some jurisdictions, IT cooperates across departments to place hot spots in strategic locations, such as in public parks. This gives workers a reliable, high speed connection, at a location where they can park vehicles to upload reports and download information. Wi-Fi connections are especially useful for data-intensive tasks that can bog down available bandwidth on a cellular network, such as updating maps and images, as well as downloading patches, software updates and antivirus signatures.

Software

For standardization, nearly all mobile devices that are used for complex tasks and applications run versions of the Microsoft® Windows® operating system to support the most common applications.

Key applications that are primarily used across government agencies include:

- CAD (Computer-Aided Dispatch) applications, which are the workhorses of public safety deployments including police, fire and paramedic services. CAD applications for law enforcement have historically been the initial focus of a governmental mobile rollout.
- RMS (Records Management Systems) for filing incident reports.
- Mapping and GIS software for route finding and vehicle / device tracking.
- General-purpose Internet applications including e-mail clients and Web browsers. These access departmental e-mail, intranets and the many applications that use a browser-based front end. Access to the broader Internet may be needed for some job functions, or available for private use as allowed by the departmental security policies.
- Database applications that offer access to state and federal databases containing criminal records and driver's license information; pre-filed response plans for fire departments; health records and other information.
- Scheduling, job tracking, time-tracking and other applications as necessary for the organizational mission.

Mobile devices are tools that workers use in the everyday course of doing their jobs. Like any other tool, workers simply expect them to work. They cannot be bothered to update software, tweak network settings, or deal with the minutiae of configuring their devices. If the system is difficult to use, they won't use it.

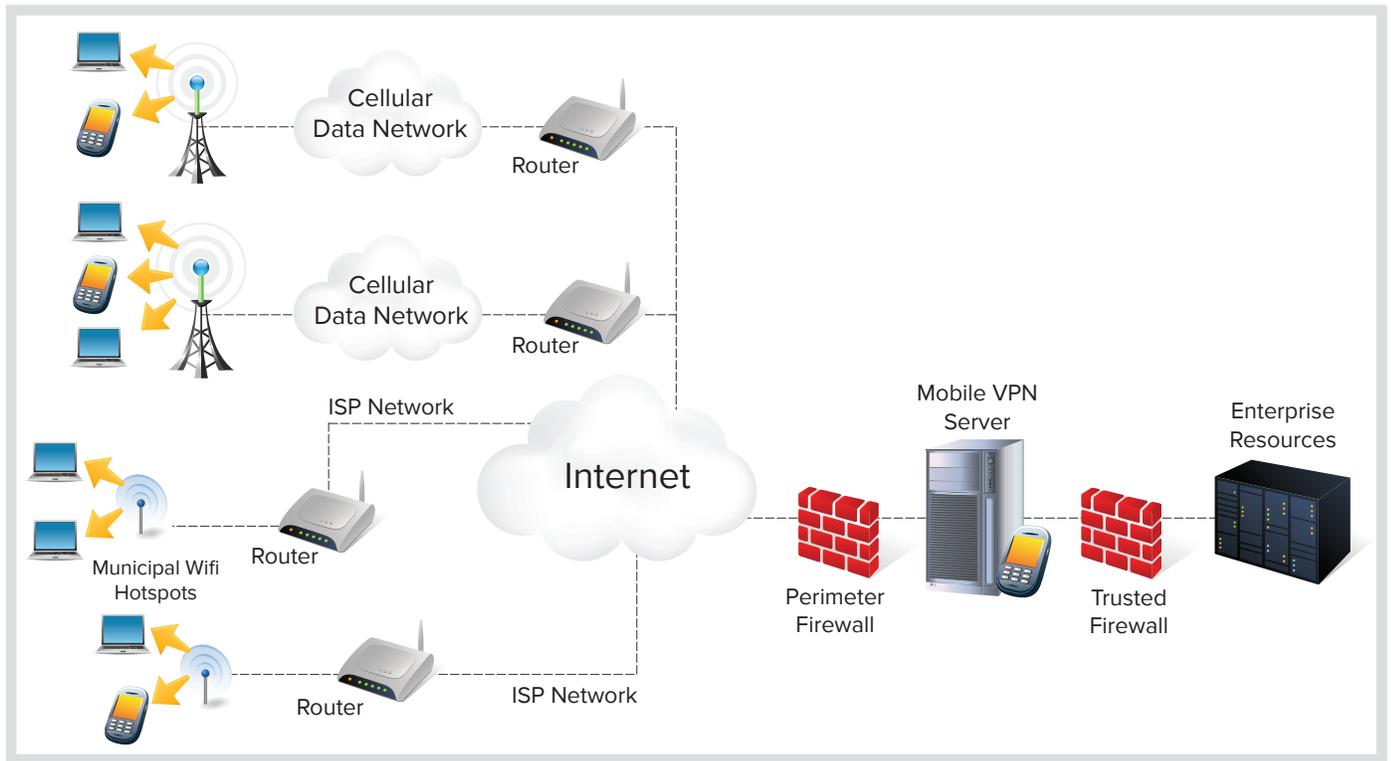

However, there is also a class of users who know too much, but not enough. They might attempt to "adjust" or "improve" their devices and break critical settings in the process.

Remote management gives the IT department centralized control and visibility over the installed applications, application versions, configuration, security and status of every mobile device. The larger the deployment, the more essential a remote management system becomes.

A VPN handles the vulnerability issues of sensitive or privileged data sent over the public airwaves or the Internet. A mobile VPN is a special class of VPN, distinct from IPsec or SSL VPNs. The most essential characteristic of a mobile VPN is that it maintains a secure tunnel through conditions that would break a conventional VPN, such as going out of coverage range or crossing from one wireless network to another.

A mobile VPN is a necessity in a remote deployment, where workers need applications and connections to be always on, always available. It can also be a logical evolutionary tool as a mobile worker's needs change from accessing one or two field applications to full desktop-like functionality. Whereas an SSL or IPSec VPN cannot manage the vagaries of wireless network connectivity, a mobile VPN is specifically designed for these challenges.

Many organizations have attempted mobile deployments using conventional VPNs or relied on the encryption technologies built into wireless networks, and discovered the need for a mobile VPN after the fact. Once they implemented a mobile VPN, their networking and device problems disappeared and support incidents reduced while worker uptime increased.

Mobile devices communicate via multiple cellular data networks or Wi-Fi hotspots in the field, to connect to departmental resources via the public Internet. A mobile VPN secures the connection end-to-end and maintains reliable connections as each device moves between the various networks.

The Unseen Challenge: Seamless Connectivity

A mobile VPN solves the single, most vexing problem impacting mobile deployments: maintaining application and user log-in sessions. Continuous connectivity is not always present in a wireless environment. When users lose their connections, sessions drop, applications often crash, and users have to re-authenticate to the network.

All too often, these problems don't become evident until after an organization has deployed a system, or added applications that aren't mobile-aware. Especially unfortunate, agencies often live with the problems, accepting decreased functionality and productivity because they are unaware that implementing a mobile VPN can solve the problems, quickly and efficiently.

Common connectivity issues include:

Coverage Gaps

Nearly all cellular networks have local "dead zones". When workers go out of range, they lose their connections. When they have to re-login or re-enter the data they lost, at the very least it impacts productivity. In some cases – during a police or fire response – an inability to connect or an abruptly lost connection can be life-threatening.

A mobile VPN is able to maintain a virtual connection to the application, even though the actual connection may be lost. It also preserves the state of the application, even in the middle of a data transmission, by holding the unsent or pending data in queue. The session simply resumes when the connection is available again.

Mobile VPNs are able to maintain virtual connections no matter the location of the worker and mobile device.

Use of Multiple Networks

As noted previously, the majority of agencies need multiple networks to cover the entire jurisdiction. When crossing a network boundary, responders need to log in to each new network to authenticate. They may cross these boundaries dozens or hundreds of times a day. Even applications written specifically for mobile environments (many CAD applications, for instance) cannot handle crossing of network boundaries, and require users to re-authenticate.

A mobile VPN handles multiple networks by maintaining a virtual IP address for each device. As the device encounters a new network, it authenticates to the new network, transparently to the user, and receives a local IP address from the network's DHCP server. The mobile VPN maps the virtual IP address to the local IP address so that even as the local IP address changes, the deployment operates as if it were a single network.

Suspend/Resume Cycles

For devices running on battery power, suspending a device puts it in a lower-power state. For health or social services workers doing home visits, this may be required so the device makes it through the working day on a single charge. Typically, suspending cuts power to the wireless system, breaking the connection.

A mobile VPN preserves the virtual connection through a suspend-and-resume event.

Application Reliability

Virtually all applications assume a permanent network connection. If the connection disappears in the middle of a network operation, the application typically can't re-establish access and crashes. Since many applications perform network operations in the background, at undefined intervals, the user doesn't even have to be actively using the application. And yet, an application failure can occur requiring re-logging in and retyping any lost data.

Special-purpose applications developed specifically for mobile deployments, such as CAD applications, are generally written with mobile environments in mind. Their store-and-forward capabilities allow them to survive through broken connections. Although store-and-forward applications present a workaround means of solving reliability issues, more agencies are opting for solutions that offer real-time access, making a mobile VPN a better option.

In addition, general purpose applications such as Web browsers and e-mail clients, office productivity, scheduling and resource-management systems, public-health applications, generalpurpose databases, mapping software, video camera software and others that are increasingly used in public agencies are prone to crash in a mobile environment. These application crashes are most often the greatest source of worker frustration in a typical mobile deployment. And solving them is considered one of the most important, most welcome attributes of a mobile VPN.

Support Concerns and User Acceptance

Agencies that have deployed a mobile solution without using a mobile VPN know that sporadic coverage and crashes result in chronic reliability problems, frustrate users and trigger a high number of calls to the help desk.

Public workers are serious about their mission. Technology that makes it easier will be accepted. Technology that gets in their way won't. A mobile VPN does its work in the background, handling logins and the complexities of roaming between networks while maintaining applications through coverage gaps. To users, it appears they are constantly connected to a single, seamless network.

Managing a Mobile Deployment

Mobile devices may be used hundreds of miles away from the data center, on unseen networks, far out of reach of the IT department. Workers may bring their device onsite only at the beginning or end of a shift, and in some cases, not at all. This leads to management challenges far beyond those encountered with fixed machines on a wired network.

Visibility

The total value of a mobile deployment represents a major investment of taxpayer dollars and with it comes a responsibility to ensure resources are used wisely. While a mobile VPN typically is a fraction of the total deployment cost, it allows use of the entire system to be centrally configured, managed, and observed. A mobile VPN with analytics capability goes a step further, furnishing reports that reveal patterns of use, how devices and networks are being employed, and how they might be used more wisely.

Control

Managing even a handful of remote devices can be a chore. In a large deployment with hundreds or thousands of devices it can be impossible without an automated solution. A mobile VPN with a central console makes it easy to quarantine devices that are misused, lost or stolen. Policy management capability allows administrators to dictate how devices and applications use the networks, to maximize productivity. And policies may be assigned to individual users or groups of users, affording flexible, streamlined control with permissions based on job function or organizational role.

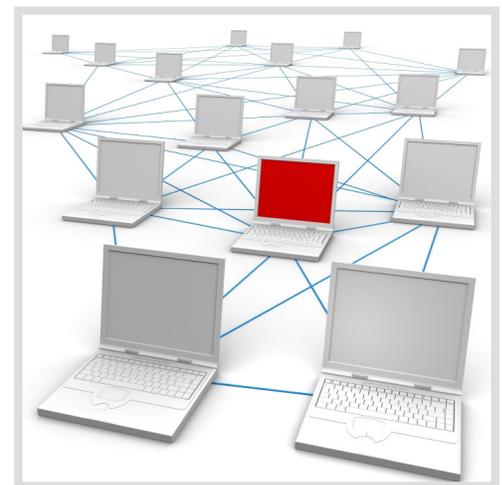

Ideally, these policies are stored on the VPN server, rather than on the mobile device, and pushed down automatically to the device where they are enforced. A well-defined set of policies locks down a device tightly, which prevents users from tinkering with settings that might override essential security or impair the functionality of the device.

System Management

A large mobile deployment may include hundreds or thousands of individual mobile devices. Tasks such as operating system upgrades, software rollouts, driver changes, updates and configuration changes which are simple in a small LAN environment are incredibly complex in a mobile deployment where devices are constantly on the move. The problems compound when a mobile deployment serves multiple government agencies, as the application profile for a first responder's device is radically different from that used by a health department worker.

System management includes:

- Staging of new devices or those returned from the service center;
- Standardizing software versions and configurations within and across various types of users; and
- Pushing out application updates, device refreshes, and security and network settings with minimal impact or interruption to the user.

Mobile deployments can be incredibly complex and problems can be compounded when a deployment serves multiple government agencies.

While system management in LAN environments is a mature industry, mobile environments pose additional challenges surrounding roaming, intermittent connectivity and variable bandwidth. A management system especially designed for a mobile environment, tightly coupled with a mobile VPN that is “connection and bandwidth-aware,” presents an ideal solution for large government deployments.

Monitoring

With workers far removed from IT resources, any problem with a device or network takes much longer to correct, possibly resulting in a dramatic loss of productive hours. A mobile VPN with proactive monitoring capabilities not only detects active problems, but when problems might be imminent. This includes problems with networks, or with a device itself such as a battery that might be failing.

Fault Isolation and Resolution

In a mobile deployment, access points may be at remote locations. Or, in the case of cellular data networks or workers using wireless “hotspots” in public locations, entire pieces of the delivery network are outside of IT control. Knowing when a problem might exist at a Wi-Fi access point, within a cellular network, or with the device itself can be problematic. A mobile VPN with a reporting and analytics capability can quickly evaluate connectivity problems across networks and isolate an individual device, network, user or time of day, detecting root causes that otherwise would take hours of sleuthing at the device level.

Bandwidth Management

Data access contracts with cellular carriers represent a sizable investment of public funds that must be used wisely. A mobile VPN that uses application-proxy technology is able to examine the complete traffic flow and how users, devices and applications use bandwidth across each cellular network. Developing reports on these areas allows administrators to understand when:

- Total bandwidth use is approaching the contracted limit and agreements may need to be renegotiated;
- Data-intensive applications (such as streaming media over Web browsers) might be wasting a public resource;
- Non-essential applications are being used; and
- Large file transfers are running over a cellular network that could be more cost-effectively handled over a wired or Wi-Fi connection.

Worker Productivity

An application-proxy mobile VPN can also proactively ensure that individual users and devices use applications and networks properly. Policy management capabilities afford extremely effective control over user and device behavior, with granular control by application, port and IP address over various networks. This ensures proper use of mobile devices which are not personal devices, but a public resource. And even workers who are using their devices as intended can accidentally launch a process, such as initiating an anti-virus signature download or running Windows updates over a cellular data connection which can bog down their device for many minutes.

Authentication

Ensuring that users are authorized is a key concern for any network manager, but this situation is of greater concern in a mobile deployment where devices are prone to be misplaced, lost or stolen. Law enforcement

agencies face increasingly stringent requirements for strong two-factor authentication, which is required to access federal criminal databases.

A mobile VPN ensures users are authorized by enforcing secure logins using either its own native active directory, or integration with an enterprise directory. Proactive notification capabilities alert administrators when a device has exceeded the number of allowed login attempts, indicating it may have been stolen, with centralized controls that quarantine the device so it cannot be used to access sensitive applications and data. Allowances for smart cards, RSA SecurID, digital certificates, biometric scanners and other two-factor authentication methods add the strong authentication required by federal mandates.

End-to-End Security

Wireless networks use the public airwaves which clearly poses security risks. And while Wi-Fi and cellular networks offer their own security technologies, some have known vulnerabilities. In addition, the portion of the route that runs over the wired Internet remains unencrypted. A mobile VPN creates a secure end-to-end tunnel that encrypts the complete data session from the corporate data center to the wireless device.

In addition, mobile VPNs may also offer Network-Access Control (NAC) capabilities that help protect both the individual device and the corporate network against viruses and spyware. It accomplishes this by verifying that security measures are active, enabled and up-to-date, and that the device has all necessary security patches as specified by the corporate security policy. Some solutions can even remediate the device automatically, without requiring any user intervention. This protects the device and guards against lost productivity, since some malware can severely degrade device performance or burden the network with malicious traffic.

The Challenges of Mobile Deployments and the Role of a Mobile VPN

Report Class/Name	Challenges	Solutions
Security		
Data security	Safety of data from compromise as it traverses airwaves and the public internet	Highest-standard FIPS 140-2 validated AES encryption secures data sessions as devices traverse networks
Device health	Protection of individual devices against viruses, spyware and other malware that can expose data	Network Access Control verifies that every device is compliant with organizational security standards before allowing a connection
Device loss or theft	Devices that are constantly in motion, and prone to being misplaced, forgotten or left unguarded	Central controls make it easy to quarantine devices that are misused, lost or stolen
Compliance	Complying with specific security standards, as required by government mandates	Support for strong authentication meets CJIS security policy requirements
Productivity		
Intermittent connectivity	Application crashes and/or repeat logins as workers cross network boundaries, go out of range, or suspend-and-resume devices	Mobile-aware VPN handles complexities of dealing with coverage gaps and roaming between networks, so public workers can focus on serving the public
Variable bandwidth	Data-intensive processes running over slower networks, bogging down device performance	Policies control device and application behavior, and keep data-intensive processes off slower networks.
Multiple networks	Isolating users from complexities of managing devices on multiple networks	Devices automatically use fastest available connection and log in automatically when roaming between departmental Wi-Fi hotspots and multiple cellular data networks
Web performance	Slow performance and page refreshes when using Web applications over cellular networks	Compression and optimization techniques improve throughput and application responsiveness

Report Class/Name	Challenges	Solutions
Management		
Bandwidth usage control	Ensuring intelligent use of a public resource, especially contracted cellular networks	Analytics capability reports on all aspects of user, device and application use, over all networks
Control and visibility	Effective, efficient management of hundreds or thousands of devices deployed in the field	Browser-based administrative console allows all aspects of the system to be centrally configured, managed and observed
User issues	Technically unsophisticated users	User-proof design is transparent, extends centralized control over configuration and minimizes trouble tickets
Troubleshooting	Fault isolation for mobile devices using multiple networks	Reports with drill-down capability uncover problems related to various data networks, time of day or other patterns of use
Monitoring	Need to continuously monitor or “babysit” the deployment	Automated notifications promote hands-off management, including pre-emptive detection of conditions that indicate failure might be imminent

Reliability to Go: NetMotion Wireless Mobility XE Mobile VPN

Mobility XE® from NetMotion Wireless is an award-winning mobile VPN that presents an elegant, single solution to all of the challenges of mobile deployments. Mobility XE:

- Keeps application sessions alive to prevent crashes as users encounter no-coverage zones, suspend and resume their devices or cross network boundaries
- Allows applications that were not written specifically with mobile deployments in mind to be used successfully in a mobile environment
- Automatically handles logins on behalf of the user, as well as the technical complexities of configuring for each connection as devices switch between networks
- Authenticates each user, through Mobility XE's own user database or integration with Windows Active Directory
- Supports strong "two-factor" authentication, a requirement for accessing the federal CJIS database in newly procured systems and a mandated retrofit for existing systems by 2013
- Encrypts all the data transmitted to protect against compromise, using the AES (Advanced Encryption Standard) for the United States
- Ensures that devices have patches that are up-to-date, as well as properly configured, active and updated antivirus and antispyware protection
- Enforces proper bandwidth use by making sure that large data transfers stay off of slower networks, and that mobile computing resources are used appropriately
- Delivers intelligence on the usage and behavior of individuals, devices, applications and networks, to drive higher productivity, monitor use of public resources and fine-tune the deployment
- Does all of the above in way that is essentially invisible to the user, improves productivity, and is highly resistant to user missteps that might impair the functionality of the device
